Which machine areas deserve attention during a dealer walkaround?

The areas that deserve the most attention are the ones that reveal how the machine was used, maintained, and cared for between owners. Focus on the undercarriage or tires, the engine bay, hydraulic components, the cab and controls, and the structural areas around welds, pins, and attachments. A dealer walkaround is not just a visual once-over. It is a practical used equipment inspection that helps separate cosmetic presentation from mechanical condition.

A clean machine can still have expensive problems, and a dusty one may be mechanically sound. The goal is to look past paint and polish and study the parts that carry load, transmit power, and affect safe operation. Start with broad condition, then move into systems that would be costly or difficult to put right after purchase.

Start with the machine's outline and structure

Walk around the machine at a steady pace before touching anything. Look at its stance. Does it sit level, or does one side appear lower? Are tracks, tires, or outriggers evenly positioned? Uneven stance can point to wear, damage, or a machine that has spent much of its life working on rough ground.

Pay close attention to frames, booms, arms, and mounting points. Straight lines should look straight. Fresh paint over a small area may be harmless, but broad touch-ups can hide weld repairs or a past impact. Look for frame cracks near stress points, especially where a boom, hitch, or attachment bracket meets the main structure. Hairline cracks can be easy to miss in poor light, so view these areas from more than one angle when access is safe.

Pins and bushings deserve the same patience. Excessive movement, shiny oval wear marks, or uneven gaps can suggest long service without timely replacement. A machine that has been used hard may still be a good buy if the price reflects that wear, but the buyer needs to know what is ahead.

Study the undercarriage, tires, and ground contact

Ground contact tells a lot about how a machine has been worked. On tracked equipment, check the condition of shoes, rollers, sprockets, and track tension. Even wear across the track is a better sign than one side being badly worn. Missing bolts, bent shoes, or uneven tooth patterns can indicate neglect or heavy use in abrasive conditions.

On wheeled machines, look for even tread wear, cuts, sidewall damage, and signs that tires have been loaded beyond their intended work. A tire with low wear on one side and heavy wear

on another may point to alignment or steering issues. That matters because tires are both a safety item and a running cost.

Fluid leaks around final drives, hubs, and track motors should be treated as a clue, not a minor stain. Leaks can come from seals, fittings, or previous repairs. A small damp area may be recent, while a built-up layer of grime can suggest a longer problem. Ask what fluid is present and when the source was last checked. If the cause is not clear, a qualified technician should assess it.

Look carefully around the engine bay

The engine bay is one of the most informative areas in a used equipment inspection. With the machine shut down and access panels open, look for clean, orderly routing of hoses, wires, and clamps. Loose wiring, cracked hose surfaces, or makeshift repairs can show rushed maintenance. That does not automatically rule the machine out, but it changes the risk.

Check fluid levels and condition where dipsticks and sight glasses allow it. Oil that looks heavily contaminated, coolant that appears rusty, or fluid below the marked range should raise questions. If the seller says a cold start is possible, the machine should be started only under safe conditions and according to the maker's guidance. Noise, smoke, rough idle, and warning lamps during startup are all worth noting.

Belts, pulleys, filters, and battery terminals also deserve attention. A machine with a fresh filter and a clean battery area may have had recent servicing, but records are more useful than appearance alone. StartNewsWire treats maintenance history as one of the core parts of evaluating used construction equipment, because service evidence helps explain what the visual check cannot.

Inspect hydraulic components and attachment points

Hydraulics are central to many construction machines, so the walkaround should include hoses, cylinders, valves, and connection points. Look for wet fittings, frayed hose covers, rubbed surfaces, and clamps that appear loose or missing. Hoses that have been routed tightly around moving parts may have been replaced poorly.

Cylinder rods should be examined for scoring, pitting, or rust where they enter the body. Some surface marks can be normal on a working machine, but deep damage can lead to seal wear and contamination. Check pins at the cylinder ends as well, since looseness there affects control and can accelerate wear.

Attachment wear is another useful signal. Buckets, forks, couplers, breakers, and other attachments often show where the machine spent its working life. A bucket with worn teeth

and thin cutting edges may be normal, but cracked plates or distorted brackets can point to heavy strain. Quick couplers need particular care. Check that pins, latches, and locking parts appear complete and properly secured. Any uncertain hydraulic or coupler issue should be reviewed by a qualified professional before operation.

Check the cab, controls, and safety items

The cab can reveal daily treatment. Look at the seat, floor, switches, screens, windows, and door seals. Heavy damage inside may match rough use outside, while a tidy cab does not prove the machine has been gentle. Controls should look complete, with no missing guards or improvised covers.

Safety guards are worth close attention. Guards around rotating, moving, or hot parts should be present and correctly fitted. Missing panels may be a sign of repairs that were never finished, or of a machine used in conditions where convenience took priority. Do not bypass or interfere with any safety device. If a guard, interlock, or warning system seems faulty, the fix belongs with a qualified professional.

During test operation, listen for unusual noise and watch how the machine responds to smooth inputs. Steering, braking, lifting, and attachment movements should feel consistent. Delays, jerky movement, or erratic response can point to wear or hydraulic problems. Testing should be done only in a safe area by someone qualified to operate that type of machine.

Match the walkaround to the records

The strongest used equipment inspection connects what can be seen with what can be documented. Service records, hour readings, repair invoices, and ownership details help explain the machine's condition. If the seller claims recent work, look for matching evidence. If records are thin, treat visible wear as more important than verbal assurances.

Operating hours are useful, but they are not the whole story. A machine with moderate hours and poor maintenance can be a worse buy than one with higher hours and a clear service pattern. The type of work matters too. Hours spent in clean site conditions differ from hours spent in mud, dust, or heavy digging. Ask what the machine was used for, then compare that answer with the wear pattern.

Paperwork also affects ownership costs. Check that serial numbers match documents, that liens or finance claims are resolved, and that required inspection records are available where relevant. A machine may look impressive in person and still be difficult to register or insure if documents are missing.

Turn observations into a buying decision

A dealer walkaround works best when each finding is placed in one of three groups: acceptable wear, needed servicing, or major concern. Acceptable wear is expected on a working machine. Needed servicing can be budgeted and verified. Major concern usually involves structure, hydraulics, engine condition, safety systems, or unclear paperwork.

StartNewsWire exists to help buyers evaluate used construction equipment before purchase by looking at condition, maintenance history, major systems, paperwork, and ownership costs. That wider view matters because the cheapest machine on the yard is not always the least expensive to own.

The best result from a walkaround is not a quick yes or no. It is a clear picture of what the machine is, how it was treated, and what may need attention next. When the visible condition, records, and operating behavior tell the same story, the decision becomes much easier to judge.
