

What Feeding Without Grass Means for Horses

Feeding without grass refers to controlling a horse's diet without regular access to grazing, so the ration must provide everything the horse would normally take from pasture. That shifts the role of **horse feed** from a simple top-up to the main source of nutrients, energy, and often a significant amount of fibre. In practical terms, the diet has to work as a **forage alternative** or, at minimum, a consistent **substitute forage** alongside hay, haylage, or other conserved fibre.

A grass-free setup may suit horses in stabled management, horses on restricted grazing, or horses that need tighter control of calorie intake and bodyweight. The key is not simply to "feed more", but to create a **balanced diet** that **grain free feed UK** supports the **digestion**, maintains **gut health**, and delivers enough **protein levels, fibre, minerals and vitamins**, and suitable **energy source** for the horse's workload and condition.

Because grass normally contributes to a **diet based on forage**, removing it means the rest of the ration must be more carefully planned. The most important consideration is whether the horse needs maintenance, conditioning, or performance support. A good grass-free plan should aim for steady **feed balance**, stable **daily calories**, and feed that is appropriate for the horse's **body condition**, temperament, and digestive sensitivity.

Kinds of Horse Feed to Use Without Grass

There are **types of horse feed** that are suitable in no-grass feeding, but they are not the same. Some are designed to cover the bulk of the daily ration, while others act as **supplementary feed** to back up a forage-heavy diet. Choosing the right option depends on how much conserved forage the horse consumes, how much energy it requires, and whether you want a lower-starch or higher-energy approach.

A **complete horse feed** is one of the most useful options when grass is absent. It is designed to provide roughage, calories, protein, and vitamins and minerals in a single product, although it still is generally most effective alongside dried grass or haylage. A complete feed can be helpful for horses that find it hard to chewing long fibre, older horses, or owners wanting a easier feeding routine with fewer separate components.

A **compound feed** is a wider term for dietary blends blended from cereals, fiber sources, protein components, and added trace minerals. A number of compound feeds are formulated for working horses, others for recreational horses, and others for easy keepers. They can be beneficial where a horse needs more targeted support for body condition or training, but the **nutritional specification** should always be examined closely.

Chaff is an additional valuable part of grass-free feeding. It provides time spent chewing, supports moderate intake, and can boost palatability when blended with other ingredients. Chaff is especially helpful for horses that need a more relaxed eating pace or a bit more volume without too much starch. It can also support saliva production, which is useful for digestive comfort.

Additional popular options feature **balancer** feeds, which provide highly concentrated vitamins, minerals, and amino acids with minimal calories, and fibre-based feeds such as **fibre cubes**. For certain horses, especially those on restricted diets, a balancer plus forage and a small amount of chaff may be sufficient. For some others, a more

filling feed is needed. The right choice depends on exercise level, body condition, and the ration's overall nutrient density.

How to Develop a Well-Balanced Grass-Free Ration

Building a grass-free ration starts with the basics: forage first in its conserved form, then concentrates or balancers only as needed. Good **horse feeding rules** always place fibre at the centre of the diet, because the horse's gut is designed for steady regular intake of roughage. Even without grass, the aim should be to support the digestive tract working steadily with regular fibre meals and sensible feed rate control.

A practical way to plan the ration is to use a **horse feeding chart** as a guide for bodyweight, condition, and workload. Charts are useful for broad planning, but they do not replace observation. Every horse has individual **daily requirements**, and those needs change with age, season, workload, and metabolism. A horse in light work may need far less concentrate than a horse in conditioning or active training.

A **horse feed calculator uk** tool can help calculate the amount of feed and forage needed, especially when working out total energy and nutrient intake. It is a useful first step for assessing feed rate and identifying whether the horse is underfed, overfed, or receiving too much sugar and starch. However, calculator results should always be checked against the horse's body condition score and actual health.

Digestible fibre is especially important in grass-free feeding. Fibre is not just "bulk"; it is an important energy source for many horses and supports stable gut function. If the ration is based on hay, haylage, alfalfa, beet pulp, chaff, or fibre cubes, the horse can still receive adequate fuel without relying heavily on cereal-based feeds. This is often preferable for horses needing calmer behaviour, better digestive comfort, or lower starch intake.

A well-built ration should consider the following:

- Conserved forage as the foundation of the diet
- Whether a complete horse feed is needed or a balancer will do
- The horse's bodyweight and body condition score
- Workload, conditioning goals, and daily requirements
- Protein quality, vitamins and minerals, and overall nutrient density
- The level of sugar and starch in the complete ration

The result should be a carefully balanced ration that supports energy, muscle maintenance, and gut health without creating unnecessary digestive stress.

Horse Feed for Beginners: What You Need to Know

Horse feed for beginners should be straightforward, consistent, and appropriate for the horse's real needs. New owners often stress over choosing the "best" feed, but the first step is always assessing the horse in front of you. A solid feeding plan is based on condition score, workload, age, and the quality of available forage, not on packaging claims alone.

Reliable **horse feed advice uk** sources tend to highlight the same core point: begin with forage, then add feed only to fill gaps. If a horse is maintaining condition well on hay and a balancer, there may be no real need for a richer compound feed. If the horse is losing weight, lacking energy, or needs more support for work, then a richer feed may be appropriate.

Body condition score is one of the most valuable tools for beginners. It helps you see whether a [overweight horse feed](#) horse is too thin, ideal, or carrying too much weight. In grass-free feeding, this is especially important because a horse's calorie intake can rise quickly if feed choices are too rich. Frequent scoring helps you adjust the ration before problems develop.

Feeding frequency also matters. Horses tend to do better with smaller, more frequent meals than with large concentrates in one go. This supports a more stable digestive system and can reduce the risk of digestive upset. For some horses, three or more daily feedings are ideal; for others, two may be enough if the ration is mainly forage-based and the horse is not in hard work.

Beginners should remember that horse feed should fit the horse, not the other way around. A calm cob, a poor-doing thoroughbred, and a veteran with dental issues may all need very different solutions. The safest approach is to make changes step by step and keep the ration predictable.

Reviewing Horse Feed Companies & Popular Brands

There are many **horse feed companies** providing grass free dietary options, and brand choice often comes down to the feed's function rather than the logo on the sack. A good comparison begins with the **ingredient list**. That list shows whether the feed is primarily fibre focused, cereal-based, high in oil, or designed as a balancer or complete ration.

As an example, **spillers horse feed** is widely known for offering a broad range of products for different types of horses, from balancers and fibre feeds to condition and performance options. This makes it a useful example of how a brand may provide several feeding routes rather than one universal answer. When comparing any brand, look at whether the feed is suitable as a main ration, a partial ration, or a supplement.

The **nutritional specification** is more significant than marketing language. Check the stated levels of energy, protein, fibre, oil, starch, sugar, vitamins and minerals, and any added probiotics or prebiotics. These numbers tell you how the feed supports conditioning, recovery, and gut health. A feed with good palatability but poor nutritional balance may tempt the horse without meeting its daily requirements.

Brand comparisons should also take into account the horse's feeding style. Some feeds are highly palatable but more energy-dense, while others are designed to be lower in starch and better suited to a controlled ration. Ask whether the product is intended for maintenance, weight gain, topline support, or improved fibre intake. That keeps the choice practical and aligned with the horse's needs.

How High Does Horse Feed Cost?

Horse feed cost differs considerably depending on whether you are buying a balancer, a complete feed, a compound feed, or a specialist fibre product. When asking **how much does horse feed cost**, it is better to consider in terms of day-to-day feeding rate and overall ration cost rather than bag price alone. A cheaper bag may not be economical if the horse needs a big amount each day.

Budgeting for grass-free feeding should include forage, concentrates, and any extras such as balancers or supplements. A horse on a simple ration of hay plus balancer may cost less to feed than a horse needing a rich compound feed, but the total depends on bodyweight, condition, and workload. Calculating cost per day gives a much clearer picture of what the ration really costs.

The **daily feeding rate** is especially useful for comparison. If one feed is fed at 1 kg a day and another at 4 kg a day, the lower bag price may not be the cheaper option overall. It is also important to factor in wastage, storage, and whether the feed replaces part of the forage allowance or is only an addition.

For many horses, the most cost-effective ration is not the cheapest feed but the best match. A well-designed balanced ration can reduce waste, improve condition, and avoid overfeeding calories the horse does not need. That can save money in the long run and support better health.

Recipe for Horse Feed Mix: When and How to Make One

A **horse feed mix recipe** can be useful when you want to blend a few simple ingredients into a practical grass-free ration. It is most suitable when you understand the horse's needs and want a custom mix based on fibre, conditioning, and digestibility. For many horses, the core of the mix will be forage plus a **balancer**, with other ingredients added only if necessary.

A basic mix might include **oats** for rapid energy, **fibre cubes** for digestible filling, and chaff to improve chew time and palatability. This can suit some horses in light or moderate work, especially when additional calories are needed. However, oats are higher in starch, so they are not suitable for every horse, particularly those needing a low-starch ration.

When making a mix, the aim is not to create the most complex recipe, but the most suitable one. A fibre-led blend can often provide a better energy source for horses that need steady fuel rather than a sharp release. If the horse already gets a good balancer and enough forage, the mix may only need a small amount of cereal or conditioning feed.

Use custom mixes cautiously. Every ingredient changes the overall nutrient density, sugar and starch profile, and feed rate. If in doubt, simplify the ration rather than complicate it. The best horse feed mix recipe is the one that supports fitness, appetite, and digestive stability without drifting away from the horse's real requirements.

Common Rationing Mistakes to Avoid

One of the most frequent mistakes is ignoring the basic **horse feeding rules** and depending too heavily on hard feed while not providing enough fibre. This can upset the digestive system and heighten the risk of poor gut function. A forage-led approach remains the best foundation, even when a horse is not on grass.

Sudden diet change is another significant risk. Any change to forage, compound feed, balancer, or fibre feed should be introduced step by step. Horses need time to adjust to new ingredients and a different ration balance. Abrupt changes can unsettle appetite, manure quality, and overall comfort.

Colic is a major concern when feeding is poorly managed. While colic has many causes, unstable routines, too much starch, and low fibre intake can all contribute to digestive stress. Consistent feeding frequency, plenty of digestible fibre, and careful transitions help reduce risk.

Starch should be watched closely, especially in horses that become fizzy, reactive, or prone to digestive sensitivity. High-starch feeds can suit some working horses, but many do better with fibre-led nutrition and more measured energy release. Overdoing starch often creates more problems than it solves.

Other mistakes include:

- Feeding feed that does not match the horse's body condition score
- Picking a product without checking the ingredient list and nutritional specification
- Feeding too much too quickly instead of following sensible feed rate guidance
- Ignoring forage quality when planning the ration
- Treating all complete feeds as interchangeable

Good feeding is regular, carefully managed, and based on observation. That is the easiest route to better health and better results.

FAQ: Grass-Free Horse Feeding Questions

What horse feed is best for grass-free feeding?

The best horse feed depends on the horse's body condition, workload, and digestive sensitivity, but many horses do well on a fibre-led **complete horse feed** or a balancer plus forage. If the horse needs more calories, a compound feed or fibre-based conditioning feed may be more suitable. The ideal choice should support a balanced ration, good palatability, and stable gut health.

Can a horse to be fed entirely on complete horse feed?

A few horses can be fed largely on complete horse feed, especially if they also receive adequate forage and the product is formulated to meet daily requirements. However, most horses still benefit from some hay or haylage because fibre remains essential to digestive function. A complete feed can be the primary concentrate, but it is not always a full substitute for long fibre.

How should I use a horse feed calculator UK tool?

A **horse feed calculator uk** tool is usually used by entering the horse's weight, training load, and sometimes body condition score. It then estimates feed and forage amounts and helps you judge whether the ration is overly rich or too light. Use it as a guide, then alter based on the horse's condition, appetite, and performance.

What do I feed my horse if it has no access to grass?

If a horse has no access to grass, feed it a fibre-first ration built around hay, haylage, or another suitable forage replacement. Add a balancer, complete horse feed, or compound feed only as needed to meet daily requirements. The aim is to provide highly digestible fibre, vitamins and minerals, and the right energy source without too much starch.

How much can horse feed cost per day?

Daily cost depends on the type of horse feed, the feed rate, and how much forage the horse needs. A balancer-based diet may be low in daily cost, while a performance compound feed or conditioning ration can be costlier. The most accurate way to judge horse feed cost is to calculate the full daily feeding rate, including forage and any supplementary feed.
